

Discussion of the paper “The *power of the pen*:  
Political influences on the legislative procedure in  
Europe”

Bas Machielsen (discussant)

2023-11-06

# Introduction

- ▶ Recapitulation of research question and research objectives:
  - ▶ “What is the effect of meetings between policy-makers and (representatives of) interest groups during the legislative procedure?”
  - ▶ Meeting  $\rightarrow$  Amendment  $\rightarrow \Delta$  Benefit/cost trade-off
  - ▶ Theoretical framework:
    - ▶ New law project brings forth some costs and benefits
    - ▶ Interested parties bargain about the allocation of these costs/benefits to various groups
  - ▶ The *next* amendment can be interpreted as the *status quo* in this bargaining process
- ▶ I want to talk about: the empirical strategy, endogeneity, and the measurement and validation of some key variables

# Empirical strategy

- ▶ Suggested approach in the presentation:

$$\text{Benefits}_{s,r,a,l,t} = \alpha_0 + \gamma \text{Meeting}_{s,r,a,l,t} + X'_{s,r,a,l,t} \beta + \epsilon_{s,r,a,l,t}$$

- ▶ Where  $\text{Meeting}_s = 1$  if stakeholder  $s$  met with any legislator  $l$  between project law  $r$  at time  $t$  and project law  $r$  at time  $t - 1$
- ▶ (I am wondering if we need the index  $a$  here, as amendments are just snapshots of law  $l$  at time  $t$ )
- ▶ More importantly, changes vs. levels: I think for each amendment, you ideally want to know either:
  - ▶ The *status quo*: the level of benefits / costs incurred by each of the stakeholders
  - ▶ This might be difficult to measure / requires more far-fetched assumptions on the abilities of the LLM
  - ▶ Therefore: *change* in the *status quo*: relative to the “first” draft text, what happened?

## Empirical strategy: Independent variable

- ▶ Why no intensive margin/count variable in addition to a dummy?
  - ▶ There might be convex returns to lobbying
- ▶ Considering the wide variety of interested parties, maybe best to group them together
  - ▶ Dummy = 1 if interest group  $j \in J$  has met with *rapporteur*
  - ▶ Only real or legal persons rather than abstract entities
- ▶ The approach implies that, if a stakeholder is successful at bargaining during a meeting, this will be reflected in the *next* amendment
  - ▶ Rather than spread out over more than one amendment
  - ▶ This is the possibly the source of finding the attenuated, lower bound-influence of lobbying

## Empirical strategy: Dependent variable

- ▶ Maybe it might be interesting to look at more raw measures before investigating *benefits*
- ▶ Concretely: conditional on meeting occurring with stakeholder from category  $j$ :
  - ▶ Do we observe more changes in the project law than if there is no meeting?
  - ▶ Does the time to a new amendment decrease?
- ▶ Benefits or ( $\Delta$  benefits) might also not be a dichotomous variable
  - ▶ For example, you might distinguish between *adding* and *deleting* text, and finding out the nature of what is added or deleted

# Endogeneity

- ▶ Selection bias probably exists in an OLS approach: stakeholders select themselves into the treatment
  - ▶ Probably you do not have the intuitive counterfactual of interest yet: we want to know what would have happened compared to when the meeting did not take place *ceteris paribus*, but this is governed by choice
  - ▶ Meaning their potential outcomes probably not comparable to outcomes in the control group
- ▶ I think a possible IV strategy might focus on how the meetings are planned:
  - ▶ Are there queues for meetings?
  - ▶ Who allocates these? Are there also rejected meeting requests?
- ▶ Placebo test with an “unrelated” independent variable, e.g. meetings with secretary or with parties that have nothing to do with the law

# Empirical Strategy: Fixed Effects

- ▶ Reminder: suggested approach in the presentation:

$$\text{Benefits}_{s,r,a,l,t} = \alpha_0 + \gamma \text{Meeting}_{s,r,a,l,t} + X'_{s,r,a,l,t} \beta + \epsilon_{s,r,a,l,t}$$

- ▶  $\alpha_0$  contains a lot: what kind of fixed effects do you need?
- ▶ What are the *least important* of all of these dimensions?
  - ▶ I think: calendar time  $t$
  - ▶ So maybe: investigate temporal heterogeneity later by splitting up the sample
- ▶ You are left with  $s, r, a, l$ 
  - ▶ I think you definitely need law fixed-effects  $r$
  - ▶ Potentially legislator fixed effects  $l$
  - ▶ Law-amendment fixed effects  $a$  impossible because that is where your identifying variation comes from
  - ▶ For each stakeholder (group)  $j$  a separate meeting dummy / count

# Manual Data Suggestion

- ▶ Approach now (GPT) is a bit arcane
- ▶ Manually needed data can be used to train a language model more explicitly
  - ▶ BERT or any other standard architecture + a classifier head
- ▶ Validation approach much needed:
  - ▶ Compare answers to manually classified amendments
  - ▶ Possibly: use stock price information of stakeholders to validate 'value' of amendment
  - ▶ Could also be a dependent variable:
$$P_j = \alpha_0 + \alpha_1 \text{Amendment} \times \text{Stakeholder } j \text{ has Meeting} + \alpha_2 \text{Amendment} + \epsilon_i$$
